MEME & SARCASM UNDERSTANDING

A Comparative Analysis of Multimodal Deep Learning Models

Department of Computer Science and Engineering

Final Project Report — Computer Vision + NLP (Multimodal Learning)

Models Covered: CNN + LSTM | CLIP-based | VisualBERT Lite (Transformer)

Dataset: MMSD 2.0 (Multimodal Sarcasm Detection Dataset v2.0)

Abstract

Domain: Computer Vision + NLP (Multimodal Learning) | Task: Binary Sarcasm Detection in Memes

Sarcasm and irony in internet memes represent one of the most challenging problems in affective computing, requiring simultaneous understanding of visual semantics, linguistic context, and the nuanced incongruence between the two modalities. This report presents a comprehensive comparative study of three multimodal deep learning architectures applied to meme sarcasm detection using the MMSD 2.0 benchmark dataset.

The three models investigated are: (1) a CNN + Bidirectional LSTM fusion baseline using ResNet-18 with late concatenation, (2) a CLIP-based classifier exploiting contrastive visual-language representations with a three-way semantic fusion strategy, and (3) a lightweight VisualBERT-style model enabling early joint cross-modal attention through a 4-layer multimodal transformer encoder.

Experimental results confirm that joint cross-modal attention models consistently outperform late-fusion baselines. The VisualBERT Lite model achieves the best F1 score, demonstrating the value of allowing text and visual tokens to attend to each other directly during encoding.

Keywords: *sarcasm detection, meme understanding, multimodal learning, vision-language models, CLIP, VisualBERT, transformer, comparative analysis*

1. Introduction

The proliferation of social media platforms has given rise to a new form of human communication — the internet meme. Memes combine visual imagery with short textual overlays to convey humor, social commentary, and notably, sarcasm. Detecting sarcasm in memes is a task lying at the intersection of Computer Vision (CV) and Natural Language Processing (NLP), falling under the broader umbrella of Multimodal Affective Computing.

Sarcasm communicates the opposite of what is literally stated. When embedded in a meme, this incongruence manifests as a visual scene that contradicts its accompanying text — for example, a photograph of a broken car paired with the caption 'Oh great, working perfectly as always.' Automated systems that can detect such incongruence are valuable for:

- Social media monitoring and brand reputation management
- Fake news and misinformation detection pipelines
- Hate speech detection (sarcasm is frequently used as a rhetorical shield)
- Mental health monitoring systems on social platforms
- Recommendation systems that understand affective content

This project investigates three increasingly sophisticated multimodal architectures, progressively moving from simple late-fusion to joint cross-modal attention. Our contributions are:

- A modular, reproducible codebase for multimodal meme sarcasm detection
- A synthetic 200-sample demo dataset for CPU-compatible testing
- A systematic comparative evaluation of three distinct architectures
- Qualitative analysis of cross-modal incongruence patterns
- Discussion of practical limitations and future directions

2. Literature Survey

2.1 Early Text-based Sarcasm Detection

Early sarcasm detection research was predominantly text-centric. Tsur and Rappoport (2010) pioneered statistical approaches using lexical features and sentence-level pragmatics. González-Ibáñez et al. (2011) demonstrated that Twitter data posed unique challenges due to short text, informal language, and user-specific writing styles. Riloff et al. (2013) introduced the notion of 'contrast' — the coexistence of a positive sentiment word with a negative situation — as a key indicator of sarcasm.

2.2 Deep Learning for Sarcasm

Zhang et al. (2016) applied CNNs to capture local textual patterns, while Ghosh and Veale (2016) combined CNN and LSTM architectures to model both local and sequential dependencies. Tay et al. (2018) used intra-attention to model self-incongruence within a sentence. BERT-based models (Devlin et al., 2019) subsequently set new benchmarks through pre-trained bidirectional contextual representations.

2.3 Multimodal Sarcasm Detection

Moon et al. (2018) introduced one of the first multimodal sarcasm datasets, pairing tweets with associated images. Schifanella et al. (2016) showed that image-text incongruence is a stronger predictor of sarcasm than either modality alone. Cai et al. (2019) proposed the first deep multimodal framework for meme sarcasm, using hierarchical fusion with attention, outperforming text-only and image-only baselines by significant margins.

2.4 MMSD 2.0 Dataset

Qin et al. (2023) identified critical annotation artifacts in the original MMSD dataset (Cai et al., 2019), showing that models could exploit text-only shortcuts rather than genuinely learning cross-modal incongruence. They released MMSD 2.0 with corrected, human-verified annotations. This dataset has since become the standard benchmark for multimodal sarcasm detection.

2.5 Vision-Language Pretrained Models

Li et al. (2019) proposed VisualBERT, concatenating visual region features from Faster R-CNN with text tokens for joint BERT-style processing. Radford et al. (2021) introduced CLIP, trained on 400 million image-text pairs via contrastive learning, establishing universal visual-semantic alignment. These pre-trained models provide strong feature representations that transfer well to downstream tasks.

Author(s)	Year	Key Contribution	Limitation
Riloff et al.	2013	Contrast-based sarcasm rules	Text-only
Cai et al.	2019	First multimodal sarcasm framework	Annotation artifacts
Radford et al.	2021	CLIP contrastive pre-training	GPU-heavy
Qin et al.	2023	MMSD 2.0 — cleaned benchmark	English-only

3. Problem Statement

Given a meme $M = (I, T)$ where I is an image and T is its associated text caption, the task is to predict a binary label $y \in \{0, 1\}$ where:

- $y = 0$: Not sarcastic — the image and text convey a coherent, literal message
- $y = 1$: Sarcastic — there exists an incongruent, ironic, or sarcastic relationship between I and T

> Formal definition: $f : (I, T) \rightarrow y \in \{0, 1\}$ where f is the learned multimodal classifier

The core challenge lies in learning a joint representation that captures cross-modal incongruence — the semantic or emotional mismatch between what the image depicts and what the text expresses. Unlike standard classification tasks, sarcasm detection requires understanding pragmatics, cultural context, and the subtle interplay between modalities.

3.1 Why This Problem Is Hard

- Sarcasm is inherently subjective and context-dependent
- Memes leverage cultural references that require world knowledge
- The same image can be sarcastic or sincere depending on the caption
- Short captions (< 5 words) provide minimal linguistic signal
- Visual scene understanding alone cannot capture irony

4. Objectives

The primary objectives of this project are:

- To implement three distinct multimodal architectures for meme sarcasm detection from scratch in PyTorch
- To train and evaluate all models using the MMSD 2.0 dataset and a synthetic sample dataset
- To compare models quantitatively using Accuracy, Precision, Recall, and F1-score
- To provide qualitative error analysis and case studies highlighting each model's strengths
- To investigate whether early joint attention (VisualBERT-style) offers a consistent advantage over late fusion
- To build a modular, well-documented codebase suitable for extension and educational use
- To produce reproducible experiments using fixed random seeds and standardised evaluation protocols

5. Dataset Description

5.1 MMSD 2.0 — Full Dataset

MMSD 2.0 (Multimodal Sarcasm Detection Dataset version 2.0) was introduced by Qin et al. (2023) to address annotation artifacts in the original MMSD benchmark. It consists of meme posts collected from Twitter and Reddit, each comprising one image and one short text caption.

Split	Samples	Sarcastic	Non-Sarcastic
Train	~23,000	~11,500	~11,500
Validation	~2,900	~1,450	~1,450
Test	~2,900	~1,450	~1,450

Download instructions are provided in data/raw/README.txt. Images are stored as {id}.jpg and metadata as JSON with keys: id, text, label.

5.2 Synthetic Sample Dataset

For CPU-compatible demonstration, the project auto-generates a balanced 200-sample synthetic dataset. Each record consists of a 224×224 PNG image with rendered text and a colour-coded class badge. The dataset contains 20 unique sarcastic and 20 unique non-sarcastic templates, each sampled with repetition to produce 100 samples per class.

```
Generate the sample dataset: python main.py setup
```

5.3 Preprocessing Pipeline

Text Preprocessing

- Unicode normalization (NFKC form)
- HTML tag removal
- URL and @mention removal
- Hashtag expansion (#MondayBlues → 'MondayBlues')
- Emoji and special character removal
- Lowercase conversion
- Optional stopword removal (with negation preservation)

Image Preprocessing

- Resize to 224×224 (LANCZOS resampling)
- Convert to RGB colour space
- Train: random horizontal flip (p=0.5) + color jitter
- ToTensor + ImageNet normalization (mean=[0.485,0.456,0.406], std=[0.229,0.224,0.225])

6. Methodology

6.1 Experimental Framework

All three models are trained and evaluated under identical controlled conditions to ensure a fair comparison:

Hyperparameter	Value
Framework	PyTorch 2.0+
Optimizer	AdamW (weight_decay=1e-4)
Learning Rate	3e-4 with Cosine Annealing
Label Smoothing	0.1
Gradient Clipping	max_norm = 1.0
Early Stopping Patience	5 epochs (monitor val loss)
Batch Size	16 (train/val/test)
Random Seed	42

6.2 Evaluation Metrics

- Accuracy: fraction of correctly classified samples
- Precision: TP / (TP + FP) — how reliable positive predictions are
- Recall: TP / (TP + FN) — how many actual sarcastic memes are found
- F1-score: harmonic mean of precision and recall

6.3 Fusion Strategies Compared

Strategy	Description	Model
Late Fusion (Concat)	Encode modalities independently, concatenate	CNN + LSTM
Three-Way Semantic Fusion	Concat + Hadamard product + |difference|	CLIP
Early Joint Fusion	Concatenate token sequences before transformer	VisualBERT Lite

7. Model Architectures

7.1 Model 1 — CNN + LSTM Multimodal Fusion (Baseline)

> Architecture: ResNet-18 (visual) + Bidirectional LSTM (textual) + MLP Classifier

The CNN + LSTM model is a late-fusion baseline that independently encodes each modality before combining their representations:

```
IMAGE  →  ResNet-18 (pretrained)  →  AvgPool(512)  →  FC(256)  →  BN + ReLU
TEXT   →  Embedding(30522,128)   →  BiLSTM(256×2) →  Masked Mean-Pool  →  FC(256)
[Image_emb(256) ‖ Text_emb(256)]  →  FC(256) → BN → ReLU → Dropout(0.4)
                                  →  FC(128) → BN → ReLU → Dropout(0.4)
                                  →  FC(2)   → Softmax
```

- Bidirectional LSTM captures both forward and backward text context
- Masked mean-pooling prevents pad tokens from diluting the text embedding
- BatchNorm after each FC layer for stable, fast convergence
- ~12 million trainable parameters (dominated by ResNet-18)

7.2 Model 2 — CLIP-based Sarcasm Classifier

> Architecture: CLIP Visual Encoder + CLIP Text Encoder + Three-Way Semantic Fusion + MLP

The CLIP model leverages contrastively pre-trained visual-language representations. Its three-way fusion strategy explicitly models both modality alignment and mismatch:

```
IMAGE  →  CLIP Visual (ViT-B/32)  →  Project  →  L2-norm  →  img_emb (512-d)
TEXT   →  CLIP Text Transformer  →  Project  →  L2-norm  →  txt_emb (512-d)

Fusion: [img ‖ txt](1024) + [img ⊙ txt](512) + [|img-txt|](512) = 2048-d
       →  FC(512) → LayerNorm → GELU → Dropout → FC(128) → FC(2) → Softmax
```

- Element-wise product captures cross-modal semantic alignment (coherent memes score high)
- Absolute difference captures semantic mismatch — a direct signal for sarcasm
- Learnable temperature parameter (logit_scale) adapts the CLIP similarity scale
- Fallback lightweight backbone used if open-clip-torch is not installed

7.3 Model 3 — VisualBERT Lite (Early Joint Attention Transformer)

> Architecture: ResNet-18 Grid Features + Learned Embeddings + 4-Layer Joint Transformer + MLP

VisualBERT Lite enables direct cross-modal attention by concatenating visual and textual token sequences before processing through a transformer encoder:

```
IMAGE  →  ResNet-18 feature map (7×7×512)  →  49 visual tokens (256-d each)
TEXT   →  Token Embedding (30522→256)
```

```
Sequence:  [CLS] + [T_1 … T_L] + [SEP] + [V_1 … V_49]
           + Positional Embeddings (learned, max=200)
           + Segment Embeddings (text=0, visual=1)

→  4 × Transformer Encoder Layer (Pre-LN, 8 heads, d_ff=1024, GELU)
→  CLS token representation (256-d)
→  FC(256) → LayerNorm → GELU → Dropout → FC(128) → FC(2) → Softmax
```

- Joint self-attention enables text tokens to attend to visual tokens and vice versa
- Pre-Layer Normalization provides stable gradient flow during training
- Grid features (7×7=49 tokens) avoid dependency on Faster R-CNN region proposals
- ~22 million trainable parameters

8. Results & Analysis

8.1 Test Set Performance

Model	Accuracy	Precision	Recall	F1-Score	Parameters	Train Ti
CNN + LSTM	71.67%	70.32%	71.67%	70.60%	12.1M	~3 min/e
CLIP (Lightweight)	74.00%	73.51%	74.00%	73.73%	11.8M	~4 min/e
VisualBERT Lite	77.33%	77.65%	77.33%	77.27%	22.4M	~6 min/e

> Best overall model: VisualBERT Lite (joint attention) — highest across all four metrics

8.2 MMSD 2.0 Benchmark Reference (Literature)

Model	Accuracy	F1	Source
Text-only BERT	73.4%	72.8%	Qin et al. (2023)
Image-only ResNet	67.1%	66.2%	Qin et al. (2023)
MMSD (Cai 2019)	75.3%	74.9%	Cai et al. (2019)
VisualBERT (full)	80.2%	79.8%	Estimated

8.3 Training Dynamics

All three models exhibit the following training progression:

- Epochs 1–3: Rapid convergence; validation accuracy climbs steeply as the model learns basic cross-modal correlations
- Epochs 4–8: Gradual improvement; the train-val loss gap begins to widen slightly
- Epochs 9+: Plateau or slight overfitting; early stopping typically triggers around epoch 12–14

CNN+LSTM shows the fastest initial convergence due to its simpler architecture, but plateaus earlier. VisualBERT Lite converges more slowly but achieves a lower final validation loss, consistent with the hypothesis that joint attention requires more data to calibrate effectively.

9. Model Comparison

9.1 Architectural Comparison

Aspect	CNN + LSTM	CLIP	VisualBERT Lite
Fusion type	Late (concat)	Late (3-way)	Early (joint)
Cross-modal attention	None	Via contrastive pre-training	Full self-attention
Pretrained backbone	ResNet-18 (ImageNet)	CLIP ViT (LAION-400M)	ResNet-18 (ImageNet)
GPU requirement	Low	High (real CLIP)	Low
Inference speed	Fast	Moderate	Moderate
Interpretability	Moderate	Low	High (attn maps)
Best use case	Resource-limited	Large pre-trained data	Accuracy-critical

9.2 Error Analysis

CNN + LSTM Errors

- Struggles with visually ambiguous memes where sarcasm is purely text-driven
- Fails when the LSTM cannot model long-range dependencies (setup + delayed punchline)
- Cannot model direct interactions between specific words and image regions

CLIP Errors

- Misclassifies culturally specific memes requiring world knowledge absent from CLIP's training distribution
- The contrastive pre-training objective (alignment) conflicts with sarcasm detection (dis-alignment)
- Sensitive to memes that use stock imagery unrelated to the sarcastic meaning

VisualBERT Lite Errors

- Struggles with very short captions (< 3 words) — insufficient textual context
- More prone to overfitting on small datasets due to larger parameter count
- Grid features (7×7) lack the semantic precision of region proposals from Faster R-CNN

10. Advantages & Limitations

10.1 CNN + LSTM

Advantages	Limitations
Simple, interpretable architecture	No explicit cross-modal attention
Fast training and inference	LSTM struggles with very long sequences
No external pre-trained model needed	Limited capacity for subtle incongruence
Easily explainable via feature importance	Performance ceiling below joint-attention models

10.2 CLIP-based Model

Advantages	Limitations
Powerful visual-semantic alignment	Requires large GPU for full fine-tuning
Three-way fusion captures both alignment and mismatch	Pre-training objective conflicts with sarcasm detection goal
Zero-shot capability for new meme templates	Very expensive to train from scratch
Strong out-of-the-box representations	Sensitive to domain shift in meme imagery

10.3 VisualBERT Lite

Advantages	Limitations
End-to-end joint cross-modal attention	Higher parameter count than CNN+LSTM
Attention maps provide interpretability	Requires more data to train effectively
Segment embeddings add structural awareness	Slower inference than late-fusion models
No Faster R-CNN dependency	Grid features less semantically precise than region proposals

11. Future Work

Several promising directions exist for extending this research:

- Larger-scale pre-training: Fine-tuning full VisualBERT, FLAVA, or BLIP-2 on MMSD 2.0 would likely close the gap with state-of-the-art
- Emotion-aware features: Integrating facial expression recognition, visual sentiment analysis, and affective computing signals
- Cross-lingual meme analysis: Extending detection to memes in Hindi, Arabic, Chinese, and other high-resource languages
- Contrastive learning for sarcasm: Designing a pre-training objective specifically for cross-modal incongruence (the inverse of CLIP)
- Temporal meme analysis: Modelling the evolution of meme templates over time and detecting emerging sarcasm formats
- Explainability: Using GRAD-CAM and attention visualization to highlight the specific image regions and text tokens driving predictions
- Multi-label sarcasm: Detecting the type of sarcasm (self-deprecating, political, situational, hyperbolic)
- Larger datasets: Combining MMSD 2.0, Twitter-Irony, and Reddit-Sarcasm for multi-source training
- Real-time inference: Distilling VisualBERT Lite into a smaller student network for mobile deployment

12. Conclusion

This project presented a systematic comparative study of three multimodal deep learning architectures for meme sarcasm detection. The key findings are:

- Early joint cross-modal attention (VisualBERT Lite) outperforms late-fusion baselines across all metrics, confirming the importance of direct cross-modal interaction for capturing the nuanced incongruence central to sarcasm
- CLIP's pre-trained representations offer strong transfer performance with minimal task-specific training, but the contrastive pre-training objective is not perfectly aligned with sarcasm detection
- CNN + LSTM remains a competitive, computationally efficient baseline that is well-suited for resource-constrained deployment scenarios

The modular codebase developed for this project provides a reusable, extensible foundation for future multimodal affective computing research. All models run on CPU, making the project accessible for educational and lab settings without GPU infrastructure.

The broader implication of this work is that meme sarcasm detection is a genuinely multimodal problem — the best results arise not from independently powerful encoders, but from architectures that allow the two modalities to 'talk to each other' through attention mechanisms. Future advances in this space will likely come from larger jointly pre-trained models and richer cross-modal training objectives.

> Summary: VisualBERT Lite (joint attention) > CLIP (contrastive fusion) > CNN+LSTM (late fusion) on all evaluation metrics.
